Cost-Effective, Ubiquitous Protection

Managing on-premises web security appliances is expensive and takes cycles away from security teams who are often already stretched thin. Deploying web security as a cloud service can drive down total cost of ownership. There are no longer hardware appliances to buy, own, and maintain. All resources formerly used for maintaining appliances, performing tasks such as software upgrades and patching, can be reallocated to more strategic initiatives within the IT or IT security organization.

Both appliances and the cloud service can be used together in a hybrid deployment. Most organizations choose this model to maintain ownership and control of appliances on the network and extend cloud-delivered protection to small remote offices and roaming users.

IT teams who backhaul web traffic from remote offices over multiprotocol label switching (MPLS) circuits for filtering by a web gateway appliance on network benefit immediately from cloud-delivered web security. Backhauling traffic is expensive and adds complexity to the network. Instead, remote offices can route directly to the cloud for protection, reducing MPLS circuits and simplifying network architecture.

Lastly, employee access to the web is no longer confined to the network perimeter, leaving off-network users and devices unprotected and invisible to IT. Shifting web security to the cloud inverts this perimeter. Web traffic

Key Benefits

- The most cost-effective way to deploy web security—no on-premises hardware or software required.
- Go beyond basic protection—behavior emulation prevents zero-day malware in milliseconds as traffic is processed.
- Extend protection to off-network users. Cloud-delivery erases the traditional network perimeter.
- Unified with McAfee® MVISION Cloud (CASB) console for an efficient and consistent security management experience.
- Proven architecture: McAfee® Web Gateway Cloud Service is built as a multitenant version of McAfee Web Gateway, the trusted on-premises appliance used by enterprises worldwide.

McAfee Web Gateway Cloud Service

Cloud-native web security providing ubiquitous protection

Defending against sophisticated threats from the web takes advanced technology, but it doesn’t have to drive cost and complexity. Delivering web security from the cloud enables security teams to gain the same benefits of advanced threat protection as on-premises appliances but without the cost of hardware or the resources used to maintain it. As more web access occurs outside the network perimeter, the cloud becomes the consistent point of contact for devices and users as they roam. Instead of building security for traffic flowing into a single location, it is more effective to build security from the endpoint out. Unifying access control and threat protection for the Cloud and Web enables your workforce to operate with maximum productivity while creating an efficient and consistent security management experience.
from off-network users and devices can be automatically routed from the endpoint to cloud, maintaining a secure connection when users are working from home, at an airport, a coffee shop, or any other off-network location. No longer is the network focused on traffic within physical walls. Instead, it is extended out from wherever an endpoint travels.

**Global, High-Performance Architecture**

McAfee® Web Gateway Cloud Service is built for the enterprise, and many organizations will gain a higher level of performance than they currently experience on premises. For example, on premises, when there is a need for capacity increase, IT needs to procure and deploy a new appliance, which can take days to weeks. In our cloud, capacity increases take approximately 15 minutes due to the elastic cloud design built into the service.

When an on-premises appliance fails and needs repair, it can take down the internet and damage security posture if it is allowed to fail to open to the web. In the event of a failure at one of our data center locations, our cloud service will automatically re-route all web traffic to the closest, fastest data center location, ensuring immediate continuity.

Our cloud service architecture is also built to “peer” with the internet backbone at the world’s largest internet exchange points (IXPs). This eliminates routing hops of intermediate internet service providers (ISPs) which add latency to the connection. With fewer hops to popular content providers, such as Microsoft Office 365 and Google, users gain a faster connection through our cloud service than they would connecting directly to the open internet.

McAfee Web Gateway Cloud Service is global. Web content can be delivered in local regional language, so regardless of where a user connects, they see for example, local Google search results. To view the current locations and status of the data centers where web traffic is processed, visit [https://trust.mcafee.com](https://trust.mcafee.com).

**Defend Against Sophisticated Threats**

Security teams often can’t keep up with highly sophisticated malware and targeted attacks that evade traditional defenses, causing a drain on resources and constant “firefighting” to keep up with endpoint remediation. Unlike traditional URL filtering and signature-based approaches to preventing web threats, McAfee Web Gateway Cloud Service protects endpoints from zero-day and fileless malware through in-line emulation of files, JavaScript, and HTML. This enables the prevention of zero-day malware before it ever reaches a user and improves block rates by approximately 20% over URL filtering and signature-based solutions.

Security operations benefit from lower costs and greater resource flexibility by reducing the overall number of malware incidents. Anything left that is still found to be suspicious can be sent to McAfee Cloud Threat Detection, and our cloud-based advanced threat analysis solution, which is available as a complementary, natively integrated service alongside McAfee Web Gateway Cloud Service.
Web threats are often delivered through encrypted traffic to hide from web security defenses. Nearly all cloud applications, such as cloud storage or social media, use encrypted traffic by default. McAfee Web Gateway Cloud Service can fully decrypt and inspect HTTPS-encrypted traffic, enabling malware prevention and cloud application visibility within encrypted channels.

Unified Access Control and Threat Protection for the Cloud and Web

Cloud services come at multiple levels of risk and can be accessed by both managed and personal devices. The unification of McAfee Web Gateway Cloud Service and McAfee MVISION Cloud (CASB) enables control access to all cloud services and protects against threats that occur within them from a single console. The combined policies deliver unprecedented cloud control—with MVISION Cloud to perform its sanctioned cloud service visibility and control via API and reverse proxy, and McAfee Web Gateway Cloud Service to monitor and block unsanctioned cloud services and web traffic via forward proxy. High-risk cloud service will be blocked, preventing end-users from accessing these services to keep them safe from accidental data loss or malware.
